Using the renv package

renv is a package-management package, in that it stores packages relative to the R project instead of the computer. - Info is written into a lockfile, which is uploaded to git - This installs relevant packages and the version used when creating the original project

```
library (ggplot2)
library (dplyr)
```

```
##
## Attaching package: 'dplyr'

## The following objects are masked from 'package:stats':
##
##      filter, lag

## The following objects are masked from 'package:base':
##
##      intersect, setdiff, setequal, union
```

```
library(paletteer)
```

```
## Warning: package 'paletteer' was built under R version 4.5.3
```

Additional renv Notes

In the console, write `renv::init`. This downloads all packages, shows Rstudio and package versions, and creates a lock file and folder for the lock file.

- The `.gitignore` is the file stating that we don't want git tracking these packages; we don't want this because it keeps us from repeating installation
- `renv::restore` brings all the packages back that are being kept in the lockfile

Optional Material - RMoCap package

I chose to look into the RMoCap package because my lab relies on motion capture as a form of gait and movement analysis. Personally, I have used software such as OpenSim and OpenCap in the past, and may use it in the future. I would like to have a better understanding of this package so I can use it for future studies and data analysis.

The article on the RMoCap package can be found [here](#)
